

# **Store energy and close the circuit breaker at the same time**

## Overview

---

A two step stored energy mechanism is a mechanism for closing a breaker where a spring is charged (first step) and then an action is performed (second step) to close the breaker. Masterpact circuit breakers are operated via a stored energy mechanism which can be manually or motor. Supports system reliability by reducing the risks associated with electrical faults. Think of it like a coiled spring in a jack-in-the-box—except here, the “pop” saves your equipment from damage. The function of the operating mechanism is to provide a means of opening and closing the circuit breaker. Temperature management remains tricky—storing energy within breakers increases internal heat by 15-20°C.
